Abstract: Mental disorders not only affect the emotional state and social functioning of patients but may also exert long-term influences on their intimate relationships. Previous studies have primarily focused on patient symptoms or caregiver burden within family contexts, whereas comparatively less attention has been paid to the psychological experiences of romantic partners and the mechanisms underlying their emotional burden. This paper provides a conceptual analysis based on existing literature to examine the emotional burden experienced by partners in intimate relationships involving mental disorders. Drawing upon research on emotional contagion, empathic distress, and emotion regulation, the study proposes an integrative framework explaining how emotional burden may gradually develop within such relationships. Existing studies indicate that partners of individuals with mental disorders tend to report higher levels of psychological stress, anxiety, and depressive symptoms, and emotional contagion processes within intimate relationships may further amplify these effects over time. Based on these findings, the present study proposes a conceptual model of partner emotional burden in intimate relationships, highlighting the roles of empathic distress and emotion regulation difficulties in the development of psychological pressure among partners. Understanding these mechanisms may broaden current perspectives on mental health interventions and emphasize the importance of providing psychological support not only for patients but also for their intimate partners.

1. Introduction

1.1 Epidemiological background of mental disorders

Mental disorders have become a major global public health concern. According to the *World Mental Health Report 2022* published by the World Health Organization, approximately one billion people worldwide are affected by various forms of mental disorders. Common conditions such as depression, anxiety disorders, and bipolar disorder significantly impair individual functioning and social participation.

From the perspective of disease burden, mental disorders represent one of the major challenges for global health. Vigo et al. (2016) reported that mental illnesses contribute substantially to global disability-adjusted life years (DALYs). Therefore, mental health issues are no longer solely clinical concerns but have increasingly become significant topics in public health and social research.

1.2 Mental disorders and intimate relationships

Mental disorders not only influence patients' emotional and behavioral functioning but may also affect their intimate relationships. Intimate relationships are often important sources of social support; however, when one partner experiences severe emotional or behavioral problems, interaction patterns within the relationship may change.

Previous studies suggest that mental illness is associated with decreased relationship satisfaction, communication difficulties, and increased relational conflict (Whisman & Uebelacker, 2004). In many situations, partners play an important role in providing emotional support. When patients experience emotional instability or functional impairment, partners may need to invest additional effort in emotional reassurance, daily support, and crisis management. Consequently, mental disorders may produce cascading effects at the relational level rather than remaining solely an individual health issue.

1.3 Psychological burden among partners

Existing studies have already noted that family members of individuals with mental disorders may experience substantial psychological burden. Idstad et al. (2010) found in a population-based study that spouses of individuals with mental disorders reported higher levels of subjective burden and were more likely to experience symptoms of anxiety and depression.

Similar conclusions have been observed in studies of severe mental illnesses. Awad and Voruganti (2008), in their review on caregiver burden in schizophrenia, reported that family members often experience significant psychological

stress, role changes, and reduced quality of life during long-term caregiving. Although these studies primarily focus on family caregivers, they indicate that individuals who provide continuous emotional support within relationships may experience increased psychological burden.

From a relational systems perspective, mental disorders may alter the distribution of roles within intimate relationships. When emotional or behavioral difficulties occur frequently, partners may gradually assume greater responsibility for emotional support and problem management, which may increase psychological stress.

1. Theoretical Foundations and Mechanisms of Emotional Burden

2.1 Psychological burden of partners

Mental disorders not only influence patients themselves but may also exert continuous psychological effects on their partners. Studies indicate that spouses or partners of individuals with mental illness often report elevated levels of stress and subjective burden. Idstad et al. (2010) showed that partners of individuals with mental disorders were significantly more likely to experience psychological distress compared with partners of individuals without such conditions.

These findings are consistent with research on caregiver burden in severe mental illness. Awad and Voruganti (2008) emphasized that long-term caregiving responsibilities may result in psychological strain, changes in social roles, and decreased well-being. Although such research mainly focuses on family caregivers, it suggests that individuals who continuously provide emotional support within relationships may experience additional psychological burden.

2.2 Emotional contagion in intimate relationships

In social psychology, the concept of **emotional contagion** describes the process by which individuals automatically mimic and synchronize emotional expressions with others. Hatfield, Cacioppo, and Rapson (1994) proposed that people may unconsciously imitate emotional signals from others, thereby experiencing similar emotional states.

Within intimate relationships, emotional contagion may be particularly pronounced. Joiner and Katz (1999) proposed the concept of **contagious depression**, suggesting that depressive symptoms in one partner may predict increased depressive symptoms in the other partner over time.

Subsequent studies have also documented mutual influences between partners' emotional states. For example, Kouros and Cummings (2010) found longitudinal associations between depressive symptoms among couples. These findings suggest that emotional states in intimate relationships may exhibit a form of emotional coupling over time.

2.3 Empathic distress and psychological pressure

Empathy is generally considered a fundamental psychological mechanism that supports social relationships. However, empathy may also generate psychological pressure in certain contexts. Davis (1983) proposed that empathy consists of multiple dimensions, including **personal distress**, which refers to self-oriented discomfort experienced when witnessing another person's suffering.

When individuals are repeatedly exposed to others' emotional distress, empathic responses may accumulate and contribute to psychological pressure. Figley (1995) suggested that prolonged exposure to others' suffering may lead to emotional fatigue and psychological resource depletion.

In intimate relationships involving mental disorders, partners may frequently confront emotional instability or distress experienced by the patient, making them more susceptible to persistent empathic stress.

2.4 Emotion regulation difficulties

Emotion regulation is considered a key psychological resource for coping with stress. Gratz and Roemer (2004) proposed that difficulties in emotion regulation may manifest as problems in recognizing, understanding, or managing emotional experiences.

Within high-stress relational contexts, individuals who lack effective emotion regulation strategies may be more vulnerable to psychological distress. When partners continuously provide emotional support within the relationship, insufficient regulation abilities may increase susceptibility to anxiety, depression, or stress reactions. Therefore, emotion regulation ability may play a crucial role in the development of emotional burden among partners.

2. Partner Emotional Burden Model

Based on the literature reviewed above, this study proposes an integrative conceptual framework explaining the development of emotional burden among partners in relationships involving mental disorders. The proposed conceptual framework is presented in Figure 2.

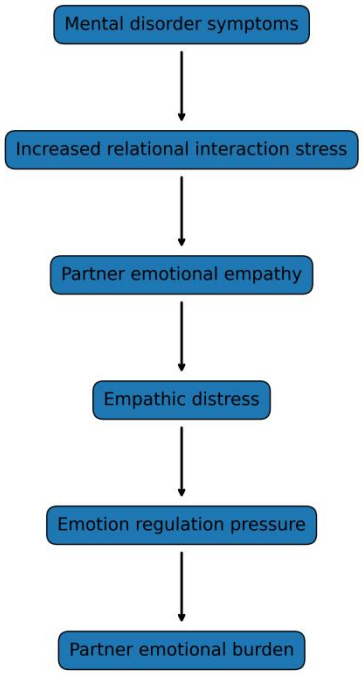

Figure 2. Conceptual model of partner emotional burden in intimate relationships involving mental disorders

The model suggests that emotional burden may gradually emerge through the following process:

Mental disorder symptoms
↓
Increased relational interaction stress
↓
Partner emotional empathy
↓
Empathic distress
↓
Emotion regulation pressure
↓
Partner emotional burden

In this framework, emotional contagion, empathic distress, and emotion regulation capacity jointly influence the psychological experiences of partners. The model emphasizes that emotional burden is not caused by a single factor but rather results from the cumulative effects of multiple psychological processes during long-term relational interaction.

3. Discussion

4.1 Relational mechanisms of partner emotional burden

The present conceptual analysis examined the mechanisms underlying emotional burden among partners in intimate relationships involving mental disorders. Existing studies suggest that spouses or partners of individuals with mental disorders often report higher levels of psychological distress and subjective burden (Idstad et al., 2010). Similar patterns have also been reported in research on caregiver burden in severe mental illness (Awad & Voruganti, 2008).

Within intimate relationships, such burden may arise not only from caregiving tasks but also from ongoing emotional interaction processes. Emotional instability, functional impairment, and social difficulties associated with mental disorders may alter interaction patterns within relationships, leading partners to assume increased responsibilities for emotional support and problem management.

Thus, the impact of mental disorders may extend beyond the individual patient and affect the relational system as a whole.

4.2 Emotional contagion within intimate relationships

Research in social psychology demonstrates that emotions may spread through interpersonal

interaction. Hatfield et al. (1994) described emotional contagion as a process in which individuals automatically mimic emotional expressions and consequently experience similar emotions.

In intimate relationships, this process may become particularly influential. Joiner and Katz (1999) suggested that depressive symptoms in one partner may predict depressive symptoms in the other partner. Subsequent longitudinal studies have also identified reciprocal associations between depressive symptoms among couples (Kouros & Cummings, 2010).

These findings suggest that emotional states in long-term intimate relationships may gradually converge through repeated interactions.

4.3 Empathic distress and psychological resource depletion

Although empathy is generally regarded as beneficial for maintaining relationships, continuous empathic engagement with another person's distress may also generate psychological strain. Davis (1983) conceptualized empathic distress as a self-oriented emotional reaction to others' suffering.

When partners repeatedly encounter emotional crises or psychological distress in their loved ones, empathic responses may accumulate and contribute to long-term psychological pressure. Figley (1995) proposed that prolonged exposure to others' suffering may lead to emotional exhaustion or psychological resource depletion.

Therefore, empathic distress may represent an important psychological mechanism through which emotional burden develops in relationships affected by mental disorders.

4.4 The role of emotion regulation

Emotion regulation ability may serve as an important protective factor in stressful relational contexts. Individuals who possess effective emotional regulation strategies may be better able to manage stress arising from emotional interactions.

Conversely, when individuals experience difficulties in regulating emotions, continuous emotional interaction within relationships may exacerbate psychological distress. Consequently, emotion regulation may moderate the development of emotional burden among partners.

4.5 Clinical and social implications

Understanding the emotional experiences of partners in relationships involving mental disorders has important clinical implications. Mental health interventions often focus primarily on patients; however, increasing evidence highlights the importance of family and relational contexts in recovery.

Providing psychological support for partners may not only improve their well-being but also contribute to better treatment outcomes for patients. Strengthening relational support systems may therefore represent an important component of comprehensive mental health care.

4.6 Limitations

This study is based on conceptual analysis and literature integration rather than empirical data. Consequently, the proposed theoretical model requires further empirical validation. Additionally, different types of mental disorders may affect intimate relationships in distinct ways, which should be explored in future research. Cultural and social factors may also influence emotional interactions within relationships and deserve further investigation.

5. Conclusion

Mental disorders may influence not only the psychological well-being of patients but also the emotional experiences of their partners. Existing research indicates that partners of individuals with mental disorders may experience increased psychological distress, while emotional contagion processes within intimate relationships may further amplify such effects.

By integrating research on mental disorders, emotional contagion, and empathy, the present paper proposes a conceptual model explaining the development of partner emotional burden. Future empirical studies may further examine these mechanisms and provide evidence for interventions aimed at supporting partners within relationships affected by mental disorders.
